EP 0 598 970 B1

Description

The invention relates to a method for forming a composite membrane, film or web of a material designed to form, for example, the outer layer of a sanitary towel, nappy or other product, for example a filtering device. In particular, the invention relates to a method in which the composite membrane or film or web is perforated to produce holes for the liquid which is to penetrate from the outside of the absorbent into the body of material contained in said absorbent.

More generally, the invention relates to a method for manufacturing a membrane or film of perforated material designed to separate two environments between which a liquid must be caused to flow in one direction, but not in the opposite direction. In the course of the following description, reference will be made especially to nappies or sanitary towels. However, it should be emphasised that the product produced by the method of the present invention may be used wherever there is a need for a membrane to be permeable to a liquid which must pass through the membrane or film in one direction only, as for example in a filtering device.

Patent US-A-4,780,352 discloses a product consisting of a nonwoven membrane with a plurality of holes distributed across the whole membrane to enable the liquid to pass through it. According to this patent, the material is perforated by passing it between two contra-rotating rollers whose peripheral speeds are equal to each other and to the speed of advance of the material itself. One of the two rollers comprises projections which perforate the material in cooperation with the other roller.

US-A-3,509,007 (considered to represent the closest prior art) and US-A-3,408,776 disclose a method and an apparatus for producing a perforated web material.

Said known apparatus includes means for feeding the web, and a pair of contra-rotating cylinders pressed against each other, between which the web is passed, a first cylinder being smooth and a second cylinder having projections.

According to the known apparatus and method the smooth cylinder is provided with an abrading surface and its peripheral speed is higher than the peripheral speed of the cylinder having projection on the surface thereof. The result is a perforated web with completely opened holes and a roughened surface.

The object of the present invention is to provide a method and an apparatus for forming a membrane and/or web and/or film making it possible to achieve a particular configuration of the holes in such a way as to direct the flow of liquid, so that it can penetrate, for example from the outside to the inside of the absorbent, but cannot then leak out of the latter.

A further object of the present invention is to provide a method for making a membrane and/or film that will efficiently isolate the material inside the absorbent away from the user's skin.

A further object of the present invention is to provide a method and apparatus for manufacturing a product in

membrane or film or composite form, able to form a barrier to delimit and separate two environments, between which a liquid must flow in one direction, but not in the opposite direction.

In essence, according to the method of the invention, the membrane and/or film is passed between a first rotating cylinder whose surface is essentially smooth and a second rotating cylinder whose surface is studded, that is it has a series of protuberances, and is pressed against the first cylinder, the peripheral speed of the smooth cylinder and the speed of advance of the membrane and/or film material being less than the peripheral speed of the studded cylinder.

This produces a slipping action whose effect on the material is to create holes by plastic deformation of the film material with a consequent but only partial detachment of the material in the holes and creation of strands of partially detached material lying in the direction in which the membrane material is fed through the two cylinders. The function of these strands is to allow the liquid to pass from one side of the membrane and/or film material to the other (more particularly, from the side on which the studded cylinder has acted towards the side that has passed in contact with the smooth cylinder) preventing the liquid from flowing back in the opposite direction.

The method according to the invention may advantageously be used with web materials of low basis weight, for example between 8 and 80 gsm. The membrane or film processed by the method of the present invention may be formed by a single membrane of nonwoven, for example of carded fibres, or of woven textile fibres (with suitable hydrophobic properties) or a plastic film. The method may also be employed on composite materials, consisting for example of two or more membranes of carded fibres or composites consisting of fibre membranes stuck to plastic film. Typically, it is possible to use a plastic film to each side of which a membrane of carded fibres has been applied. Firm sandwiching together of the layers forming the material can be achieved by the same rolling and slipping action used to create the special perforations described above.

Since the holes (and hence the strands) are very close together, the method of the present invention produces a membrane whose overall thickness may be much greater than the thickness of the initial material. For example, starting with a thickness of the membrane or film of 30 micrometres, it is possible to reach an overall thickness of 300 micrometres. This makes it possible, with a very small amount of material, to produce a membrane that is very thick and hence has very good isolating properties. This advantage is especially evident if a single, that is non-composite, film or membrane is used.

In an especially advantageous embodiment, and in particular for the efficient processing of plastic film material, such as polyethylene and its derivatives or other suitable plastic materials, either one or both of the cylinders may be heated to a suitable temperature. The heat increases the viscosity of the plastic material and hence facilitates its perforation and the deformation of the

strands of material partially detached from the base material. Advantageously, the two cylinders can be heated to temperatures that can be adjusted independently of each other. The surface temperature of the cylinder bearing the projections is preferably higher than the temperature of the other cylinder.

The pressure between the two cylinders, and hence the pressure with which the film and/or membrane material is rolled, may advantageously be variable to suit the base material being used. Also the difference in speed, and hence the slipping between the surfaces of the rotating cylinders may vary between preset limits to suit the material being used. More particularly, the slipping may vary advantageously between 10 and 50% and preferably between 15 and 25%. The temperature of the surfaces of the cylinders may advantageously be set at between 70 and 240°C and in particular between 100 and 180°C. The linear pressure between the rollers may vary between, for example, 120 and 220 kg/cm and preferably between 130 and 150 kg/cm.

To produce semifinished items for use in particular products, for example nappies for babies or incontinent persons, sanitary towels for women, and so forth, according to the method of the invention the material in film and/or membrane form may be perforated along continuous longitudinal strips or else along areas not extending the full length of the web. As a result, in the application of the membrane to the finished product, it is possible to have areas in which the liquid is able to flow (through the holes) from one side to the other, for example towards the inside of the absorbent, and completely impervious areas- across which the liquid cannot flow back. The perforated area will of course be positioned on the absorbent over the area where the flow of liquid to be absorbed arrives.

The apparatus according to the invention comprises a pair of rotating cylinders pressing against each other, between which the membrane or web to be processed is passed; a first cylinder being smooth and a second cylinder having projections to produce the perforations. Characteristically the peripheral speed of the cylinder having the projections is greater than the peripheral speed of the smooth cylinder, so that the film and/or membrane material, which is rolled between the two cylinders, is subjected to a slipping action and to a consequent plastic deformation.

Advantageously, either one or both of the cylinders may have heating means to maintain the outer surface at a suitable temperature to facilitate the processing by plastic deformation of the web material. The heating means of the two cylinders are advantageously independently adjustable.

The cylinder with the projections may comprise a series of identical projections over the whole cylindrical surface, or in localised areas, for example and in particular over annular areas, to produce a material that is perforated along defined longitudinal strips and with non-perforated areas between one strip and the adjacent strip. To produce a web with perforations over areas

bounded by non-perforated areas it is also possible, and preferable, to employ a cylinder with projections of differing heights and optionally of differing shapes, in particular such that the projections are higher in areas to be perforated and lower in areas not to be perforated. In areas with less prominent projections the web is sufficiently well rolled to ensure cohesion between the various optional layers forming the membrane, but is not perforated.

Further characteristics of the apparatus, of the method and of the product according to the invention are shown in the accompanying claims.

A clearer understanding of the invention will be obtained from the description and attached drawing, which latter shows a practical, non-restricting embodiment of the said invention. In the drawing:

Fig. 1 shows a highly diagrammatic illustration of a possible embodiment of an apparatus according to the invention;

Figs 2 and 3 show a front view and a cross section taken through III-III respectively of a portion of the studded cylinder in one possible embodiment;

Figs 4 and 5 show, in the same way as Figs. 2 and 3, a different configuration of the surface of the studded cylinder;

Figs 6, 6A and 7 show a portion of product in a plan view, in two cross sections taken along the direction of advance of the material through the apparatus and transversely to the direction of advance, respectively;

Fig. 8 shows a diagrammatic cross section of an absorbent;

Fig. 9 shows a portion of film or membrane perforated in strips; and

Fig. 10 shows a diagrammatic cross section of a portion of a cylinder provided with projections and suitable for producing a membrane or film with perforated areas bounded by non-perforated areas.

Referring initially to Fig. 1, the apparatus (in this embodiment) has means 1 for supporting a first roll R of web, which may be a plastic film. The web N is wound off the roll R1 and rewound onto a roll R2 carried by support means 3. The support means 3 have a motor (not shown) which turns the roll R2 in order to draw the web N and wind it up. Between the two supports 1 and 3 is a pair of cylinders indicated by 5 and 7 respectively. In the embodiment illustrated, the cylinder 5 is positioned underneath the web N and turns in a clockwise direction. The cylinder 5 has an outer surface defined by a layer 5A of elastically yielding material, for example rubber. This material may be the same as is typically used in equipment for the embossing of paper material in the production of toilet paper and similar products. The possibility of using a cylinder 5 having a steel outer surface is not excluded.

Interacting with the cylinder 5 is the cylinder 7 which turns in an anticlockwise direction. The two cylinders 5

and 7 are pressed against each other with a pressure that advantageously is adjustable. The cylinder 7 is studded, that is it has a worked surface with geometrically distributed projections. Possible shapes for the projections of the cylinder 7 will be described in greater detail when referring to the subsequent Figs 2 to 5 and 9.

The cylinder 7 turns with a peripheral speed greater by an adjustable percentage than the peripheral speed with which the underlying roller 5 turns. This creates a relative slipping action between the surfaces of the two cylinders and hence a rolling and slipping action within the web N which is being passed between the two cylinders 5 and 7, with consequent effects on the material which will be illustrated later with reference to Figs 6 and 7.

The cylinder 7 may advantageously be maintained at a high temperature, for example by the admission of steam or heat-conducting oil at high temperature through a pipe 9 which communicates with the interior of the cylinder 7 through a suitable rotating joint. Likewise the cylinder 5 may advantageously be heated by a similar system. As an alternative to heating by means of a heat-carrying fluid, the heating may be by means of electrical resistors or any other system suitable for the purpose.

Figs 2 and 3 show a possible design for the projections of the cylinder 7. In this embodiment, the cylinder has a grid of frustopyramidal protuberances on a square base, indicated by P1 in Fig. 3. Figs 4 and 5 show a different possible form for the projections of the cylinder 7, this form being characterised by protuberances P2 of generally frustoconical shape with a terminal portion 13 of approximately cylindrical form and a front surface 15 which interacts with the smooth surface of the cylinder 5.

Different forms of the studding of the cylinder 7 are also possible. These may be chosen to suit the aesthetic and technical requirements of the end product, and the cost of making the cylinder 7.

As the web N is passed between the cylinders 5 and 7, it undergoes a plastic deformation which results in the perforation of the material as the protuberances P1 or P2 of the cylinder 7 break through it. The material which is detached from the base material forming the web N is not completely removed but remains connected to the base material by at least a portion of the perimeter of the hole and lies in the direction of advance of the web N, that is in the direction of the arrow f shown in Fig. 1. The direction in which the partially detached material in each hole lies is determined by the relative slipping action between the two rotating surfaces of the cylinders 5 and 7. The Figs 6, 6A and 7 show a plan view and two cross sections taken through VIA-VIA and VII-VII respectively of the web N downstream of the pair of cylinders 5 and 7. Figs 6A and 7 clearly show the hole F and a strand of partially detached material indicated by A lying in the direction of advance of the material.

The strand A connected to each hole of the web N acts as a kind of nonreturn valve allowing the liquid to flow easily from the upper surface to the under surface of the web (with respect to the orientation shown in Figs

6 and 7), while it obstructs backflow in the opposite direction. When the web is used to form for example the outermost layer of a sanitary towel, as illustrated diagrammatically in Fig. 8, it is so placed that the strands are turned towards the interior of the towel, that is towards the body of absorbent material MA. In this way the liquid to be absorbed can easily flow from the outside to the inside of the towel whereas backflow in the opposite direction is practically prevented by the presence of the strands A.

The use of a plastic film for the web N offers the major advantage that the base material is practically impervious in areas without holes. As compared with a web formed by a membrane of carded fibres and/or any textile membranes, this reduces the risk of backflow of the liquid from the inside of the absorbent to the outside through the unbroken area of material N, that is the area without holes.

The use of a plastic film has the further advantage of eliminating the carding machine and/or other textile apparatuses from the production line on which the membrane is manufactured.

The method described can also be applied to composite webs, as mentioned earlier.

In certain particular applications, as for example in the manufacture of nappies for babies, it is expedient to have an outer layer that is permeable in a central area only, that is only where the urine is to flow. In the surrounding areas, however, it is expedient to prevent the passage of liquid in order to isolate the interior of the nappy from the exterior, thus avoiding any contact with the absorbed liquid. To this end, in an improved embodiment of the invention, the cylinder 7 may have areas - especially of complete or partial annular form - that are studded and annular areas that are smooth. In this case the web N that emerges from the pair of cylinders has perforated areas and nonperforated areas as illustrated diagrammatically in Fig. 9. In this figure N indicates a piece of web, that has perforated areas A1 and unbroken areas A2. In making the nappy, the web N is cut and wrapped around the body of internal absorbent material in such a way that a perforated strip or area A1 lies approximately along the centre line of that surface of the nappy which is intended to be placed against the user.

Instead of a cylinder having smooth areas and areas with projections, it is also possible to employ a cylinder having projections of differing heights, as diagrammatically indicated in Fig. 10, which shows a portion of the surface of the cylinder in a section taken through a plane passing through the axis. Fig. 10 shows an area 21 with protuberances 23 of height H, and an area 25, with protuberances 27 of height h, lower than H. The heights H and h are so determined that when the web N is rolled between the smooth cylinder 5 and the cylinder 7, perforations of the web are created in positions corresponding to the projections 23, while it is merely rolled in the area 25, with a resulting mutual sandwiching of the membranes of which it is composed, but is not perforated. The rolling between the surface of the cylinder 5 and the pro-

jections 27 does not over stiffen the material. The form shown in Fig. 10 can be made by, for example, uniform working of the surface of the cylinder 7 and then sandblasting those areas, such as 23, where the height of the projections 27 is to be reduced. Sandblasting results in projections 27 with a slightly rounded front surface, which gives an excellent action in use.

In a currently preferred embodiment, a polypropylene film has been used as the web. The linear pressure between the cylinders 5 and 7 has been set at 140 kg/cm and the percentage of slip at 18%. In other words, with a speed of advance of 40 m/min, the lower cylinder 5 turns at a peripheral speed equal to the speed of advance of the web N and the upper cylinder at a speed equal to 48 m/min. In this way excellent results have been obtained with the surface temperature of the cylinder 7 being maintained at approximately 120°C and the temperature of the cylinder 5 at approximately 110°C.

Claims

1. Method for forming a web (N) that is permeable to liquids and designed to separate two environments and to allow the liquid to flow in one direction from one of said environments to the other, in which said web (N) is caused to pass between two contra-rotating cylinders (5, 7) that are pressed against each other, one (7) of said cylinders having a surface provided with projections (P1, P2) which cause perforations in said web, and the other (5) of said cylinders being smooth, said cylinders (5, 7) having different peripheral speeds with a consequent relative slipping action between the surfaces of the two cylinders, the method being characterised in that the cylinder (7) with the projections (P1, P2) is turned at a peripheral speed greater than the peripheral speed of the smooth cylinder (5), and that the web (N) is fed at a speed lower than the peripheral speed of said cylinder (7) with the projections (P1, P2).
2. Method according to Claim 1, characterised in that at least one of the two cylinders is heated.
3. Method according to Claim 1, characterised in that both the cylinders are heated, the surface temperatures of the two cylinders being adjustable independently of each other.
4. Method according to one or more of the preceding claims, characterised in that the slipping between the two cylinders caused by the difference in peripheral speeds is between 10 and 50% of the peripheral speed of the slower cylinder.
5. Method according to Claim 4, characterised in that the slipping is between 15 and 25%.
6. Method according to Claim 2, 3, 4 or 5, characterised in that the cylinder with the projections has a surface temperature of between 70 and 240°C.
7. Method according to Claim 2, 3, 4, 5 or 6, characterised in that the smooth cylinder has a surface temperature of between 70 and 240°C.
8. Method according to one or more of the preceding claims, characterised in that the two cylinders are pressed against each other with a pressure of between 120 and 220 kg/cm².
9. Method according to one or more of the preceding claims, characterised in that the web is a membrane of woven textile fibres or a nonwoven membrane or a membrane of carded fibres.
10. Method according to one or more of Claims 1 to 8, characterised in that the web is a plastic film.
11. Method according to one or more of Claims 1 to 8, characterised in that the web is a membrane composed of a number of layers, each layer consisting of textile fibres or of a plastic film.
12. Method according to one or more of the preceding claims, characterised in that the web is perforated in limited areas.
13. Apparatus for manufacturing a perforated web (N) designed to separate two environments and to allow a liquid to flow in one direction from a first environment to the other, comprising means for feeding the web, and a pair of contra-rotating cylinders (5, 7) pressed against each other, between which the web (N) is passed, a first cylinder (5) being smooth and a second cylinder (7) having projections (P1, P2) the apparatus being characterised in that the cylinder (7) having the projections (P1, P2) turns at a greater peripheral speed than the peripheral speed of the smooth cylinder (5).
14. Apparatus according to Claim 13, characterised in that at least one of the two cylinders has heating means for heating its surface.
15. Apparatus according to Claim 14, characterised in that both the cylinders are equipped with heating means, and in that said heating means permit independent adjustment of the surface temperatures of the two cylinders.
16. Apparatus according to one or more of Claims 13 to 15, characterised in that the difference between the peripheral speeds of the cylinder with the projections and the smooth cylinder is adjustable.

17. Apparatus according to one or more of Claims 13 to 16, characterised in that the pressure between the two cylinders is adjustable.
18. Apparatus according to one or more of Claims 13 to 17, characterised in that the cylinder (7) with the projections (P1, P2) has an outer surface which has areas with projections and areas that are smooth. 5
19. Apparatus according to one or more of Claims 13 to 17, characterised in that the cylinder (7) with the projections has areas (21) with higher projections (23) and areas (25) with lower projections (27). 10
20. Apparatus according to one or more of Claims 13 to 19, characterised in that the smooth cylinder (5) has an elastically yielding cylindrical surface consisting of a covering (5A) made of a rubber material or a textile fibre. 15
21. Apparatus according to one or more of Claims 13 to 19, characterised in that the outer surface of the smooth cylinder (5) is made of metal. 20
22. A web or film product (N) with a plurality of perforations forming holes (F) passing through said web, wherein the material of the web or film, which has been removed in correspondence of each of said holes (F) is partially detached from the base material of said web and forms a strand (A) extending from one surface of said web or film and wherein 25
- the material of said strand (A) is plastically deformed,
 - and the base material is thicker in correspondence of the portion of perimeter of the hole where said strand is connected to said base material than in the portion of perimeter where said strand is detached from said base material. 30
 - the strand (A) projects over the relevant hole (F). 35
23. A web or film product according to claim 22, characterized in that it is formed by a single layer of plastic film. 40
24. A web or film product according to claim 22, characterized by a multilayer structure, including an intermediate plastic film layer and outer layers made of fibers, or a single layer structure of woven or non woven fibres. 45
25. A web material according to one or more of claims 22-24, characterized in that it has perforated areas (A1) and unbroken areas (A2). 50

Patentansprüche

1. Verfahren zur Herstellung einer Bahn (N) die flüssigkeitsdurchlässig ist und zur Trennung zweier Räume voneinander und zur Ermöglichung der Flüssigkeitsströmung von einem dieser Räume zu dem anderen bestimmt ist, wobei die Bahn (N) zwischen zwei gegensinnig rotierenden Zylindern (5, 7) durchgeführt wird, die gegeneinander gepreßt werden, wobei einer (7) der Zylinder an seiner Oberfläche mit Vorsprüngen (P1, P2) versehen ist, die Perforationen in der Bahn erzeugen, wobei die Zylinder (5, 7) unterschiedliche Umfangsgeschwindigkeiten und dadurch einen entsprechenden Schlupf zwischen den Oberflächen der beiden Zylinder aufweisen, wobei das Verfahren dadurch **gekennzeichnet** ist, daß der mit den Vorsprüngen (P1, P2) versehene Zylinder (7) mit größerer Umfangsgeschwindigkeit als die umfangsgeschwindigkeit des glatten Zylinders (5) gedreht wird und daß die Bahn mit einer Geschwindigkeit gefördert wird, die kleiner ist als die des mit Vorsprüngen (P1, P2) versehenen Zylinders (7).
2. Verfahren nach Anspruch 1, dadurch **gekennzeichnet**, daß mindestens einer der Zylinder beheizt ist.
3. Verfahren nach Anspruch 1, dadurch **gekennzeichnet**, daß beide Zylinder beheizt sind, wobei die Oberflächentemperaturen der beiden Zylinder unabhängig voneinander einstellbar sind.
4. Verfahren nach einem oder mehreren der vorangehenden Ansprüche, dadurch **gekennzeichnet**, daß der durch die unterschiedlichen Oberflächengeschwindigkeiten verursachte Schlupf zwischen den beiden Zylindern zwischen 10 und 50 % der Umfangsgeschwindigkeit des langsameren Zylinders beträgt.
5. Verfahren nach Anspruch 4, dadurch **gekennzeichnet**, daß der Schlupf zwischen 15 und 25 % beträgt.
6. Verfahren nach Anspruch 2, 3, 4 oder 5, dadurch **gekennzeichnet**, daß der mit Vorsprüngen versehene Zylinder eine Oberflächentemperatur zwischen 70 und 240°C hat.
7. Verfahren nach Anspruch 2, 3, 4, 5 oder 6, dadurch **gekennzeichnet**, daß der glatte Zylinder eine Oberflächentemperatur zwischen 70 und 240°C hat.
8. Verfahren nach einem oder mehreren der vorangehenden Ansprüche, dadurch **gekennzeichnet**, daß

- die beiden Zylinder mit einem Druck zwischen 120 und 220 kg/cm² gegeneinander gedrückt werden.
9. Verfahren nach einem oder mehreren der vorangehenden Ansprüche, dadurch **gekennzeichnet**, daß die Bahn eine Membran aus gewebten Textilfasern oder eine Vliesstoffmembran oder eine Membran aus gekrämpelten Fasern ist. 5
 10. Verfahren nach einem oder mehreren der Ansprüche 1 bis 8, dadurch **gekennzeichnet**, daß die Bahn eine Kunststoffolie ist. 10
 11. Verfahren nach einem oder mehreren der Ansprüche 1 bis 8, dadurch **gekennzeichnet**, daß die Bahn eine Membran aus einer Anzahl von Schichten ist, wobei jede Schicht aus Textilfasern oder aus Kunststoffolie besteht. 15
 12. Verfahren nach einem oder mehreren der vorangehenden Ansprüche, dadurch **gekennzeichnet**, daß die Bahn in begrenzten Bereichen perforiert ist. 20
 13. Vorrichtung zur Herstellung einer perforierten Bahn (N), die zum Trennen zweier Räume voneinander und zur Ermöglichung der Flüssigkeitsströmung in einer Richtung von einem ersten Raum in den anderen bestimmt ist, mit Mitteln zum Zuführen der Bahn und einem Paar von gegenläufig rotierenden, gegeneinandergepreßten Zylindern (5, 7), zwischen denen die Bahn (N) durchläuft, wobei ein erster Zylinder (5) glatt ist und ein zweiter Zylinder (7) Vorsprünge (P1, P2) aufweist, wobei die Vorrichtung dadurch **gekennzeichnet** ist, daß der die Vorsprünge (P1, P2) ausweisende Zylinder (7) mit einer größeren Umfangsgeschwindigkeit als die Umfangsgeschwindigkeit des glatten Zylinders (5) umläuft. 25 30 35 40
 14. Vorrichtung nach Anspruch 13, dadurch **gekennzeichnet**, daß mindestens einer der beiden Zylinder Heizmittel zum Beheizen seiner Oberfläche aufweist. 45
 15. Vorrichtung nach Anspruch 14, dadurch **gekennzeichnet**, daß beide Zylinder mit Heizmitteln versehen sind, und daß die Heizmittel eine unabhängige Einstellung der Oberflächentemperaturen der beiden Zylinder ermöglichen. 50
 16. Verfahren nach einem oder mehreren der Ansprüche 13 bis 15, dadurch **gekennzeichnet**, daß die Differenz zwischen den Umfangsgeschwindigkeiten des mit Vorsprüngen versehenen Zylinders und des glatten Zylinders einstellbar ist. 55
 17. Vorrichtung nach einem oder mehreren der Ansprüche 13 bis 16, dadurch **gekennzeichnet**, daß der Druck zwischen den beiden Zylindern einstellbar ist.
 18. Vorrichtung nach einem oder mehreren der Ansprüche 13 bis 17, dadurch **gekennzeichnet**, daß der mit den Vorsprüngen (P1, P2) versehene Zylinder (7) eine Außenfläche hat, die mit Vorsprüngen versehene Bereiche und glatte Bereiche aufweist.
 19. Vorrichtung nach einem oder mehreren der Ansprüche 13 bis 17, dadurch **gekennzeichnet**, daß der mit den Vorsprüngen versehene Zylinder (7) Bereiche (21) mit höheren Vorsprüngen (23) und Bereiche (25) mit niedrigeren Vorsprüngen (27) aufweist.
 20. Verfahren nach einem oder mehreren der Ansprüche 13 bis 19, dadurch **gekennzeichnet**, daß der glatte Zylinder (5) eine elastisch nachgiebige zylindrische Oberfläche hat, die aus einer Umhüllung (5a) aus Gummimaterial oder Textilfaser besteht. 25
 21. Verfahren nach einem oder mehreren der Ansprüche 13 bis 19, dadurch **gekennzeichnet**, daß die Außenfläche des glatten Zylinders (5) aus Metall ist. 30
 22. Bahn oder folienförmiges Produkt (N) mit einer Vielzahl von Perforationen, die durch die Bahn durchgehende Löcher (F) bilden, wobei das bei jedem dieser Löcher (F) entfernte Material der Bahn oder Folie vom Basismaterial der Bahn teilweise abgetrennt ist und einen Lappen (A) bildet, der von einer Oberfläche der Bahn oder Folie absteht und wobei
 - das Material des Lappens (A) plastisch verformt ist,
 - und das Basismaterial an demjenigen Teil des Umfangs des Loches, wo der Lappen mit dem Basismaterial zusammenhängt, dicker ist als an dem Teil des Lochumfangs, an dem der Lappen von dem Basismaterial getrennt ist, dadurch **gekennzeichnet**,
 - daß der Lappen (A) über das zugehörige Loch ragt.
 23. Bahn oder folienförmiges Produkt nach Anspruch 22, dadurch **gekennzeichnet**, daß es durch eine einzige Schicht aus Plastikfolie gebildet ist.
 24. Bahn- oder folienförmiges Produkt nach Anspruch 22, **gekennzeichnet** durch eine mehrlagige Struktur mit einer Zwischenlage aus Kunststoffolie und

Außenlagen aus Fasern, oder durch eine einschichtige Struktur aus gewebten oder ungewebten Fasern.

25. Bahnförmiges Material nach einem oder mehreren der Ansprüche 22 bis 24, dadurch gekennzeichnet, daß es perforierte Bereiche (A1) und durchgehende Bereiche (A2) aufweist.

Revendications

1. Procédé de formage d'une bande (N) qui est perméable aux liquides et conçue pour séparer deux environnements et laisser un liquide s'écouler dans un sens à partir d'un desdits environnements vers l'autre, selon lequel ladite bande (N) passe entre deux cylindres en contre-rotation (5, 7) qui sont comprimés l'un contre l'autre, un (7) desdits cylindres présentant une surface pourvue de projections (P1, P2) qui provoquent des perforations dans ladite bande, et l'autre (5) desdits cylindres étant lisse, lesdits cylindres (5, 7) présentant des vitesses périphériques différentes qui se traduisent par une action de glissement entre les surfaces des deux cylindres, caractérisé en ce que le cylindre (7) pourvu des projections (P1, P2) entre en rotation avec une vitesse périphérique supérieure à la vitesse périphérique du cylindre lisse (5) et en ce que la bande (N) est amenée à une vitesse inférieure à la vitesse périphérique dudit cylindre (7) pourvu de projections (P1, P2).
2. Procédé selon la revendication 1, caractérisé en ce qu'au moins un des deux cylindres est chauffé.
3. Procédé selon la revendication 1, caractérisé en ce que les deux cylindres sont chauffés, les températures de surface des deux cylindres pouvant être réglées indépendamment l'une de l'autre.
4. Procédé selon l'une quelconque ou plusieurs des revendications précédentes, caractérisé en ce que le glissement entre les deux cylindres provoqué par la différence des vitesses périphériques est égal à une valeur correspondant de 10 à 50 % de la vitesse périphérique du cylindre le plus lent.
5. Procédé selon la revendication 4, caractérisé en ce que le glissement est égal à une valeur comprise entre 15 et 25%.
6. Procédé selon les revendications 2, 3, 4 ou 5, caractérisé en ce que le cylindre pourvu de projections présente une température de surface comprise entre 70 et 240°C.
7. Procédé selon les revendications 2, 3, 4, 5 ou 6, caractérisé en ce que le cylindre lisse présente une température de surface comprise entre 70 et 240°C.

8. Procédé selon l'une quelconque ou plusieurs des revendications précédentes, caractérisé en ce que les deux cylindres sont comprimés l'un contre l'autre avec une pression comprise entre 120 et 220 kg/cm².

9. Procédé selon l'une quelconque ou plusieurs des revendications précédentes, caractérisé en ce que la bande est une membrane de fibres textiles tissées ou une membrane non tissée ou une membrane de fibres cardées.

10. Procédé selon l'une quelconque ou plusieurs des revendications 1 à 8, caractérisé en ce que la bande est un film plastique.

11. Procédé selon l'une quelconque ou plusieurs des revendications 1 à 8, caractérisé en ce que la bande est une membrane composée d'un certain nombre de couches, chaque couche se composant de fibres textiles ou d'un film plastique.

12. Procédé selon l'une quelconque ou plusieurs des revendications précédentes, caractérisé en ce que la bande est perforée dans des zones limitées.

13. Appareil pour fabriquer une bande perforée (N) conçue pour séparer deux environnements et laisser s'écouler un liquide dans un sens à partir d'un premier environnement vers l'autre, comprenant des moyens pour amener la bande, et une paire de cylindres en contre-rotation (5, 7), comprimés l'un contre l'autre, entre lesquels passe la bande (N), un premier cylindre (5) étant lisse et un deuxième cylindre (7) comportant des projections (P1, P2), caractérisé en ce que le cylindre pourvu de projections (P1, P2) entre en rotation à une vitesse périphérique supérieure à la vitesse périphérique du cylindre lisse (5).

14. Appareil, selon la revendication 13, caractérisé en ce qu'au moins un des deux cylindres comporte des moyens de chauffage pour chauffer sa surface.

15. Appareil selon la revendication 14, caractérisé en ce que les deux cylindres comportent des moyens de chauffage, et en ce que lesdits moyens de chauffage permettent de régler séparément les températures de surface des deux cylindres.

16. Appareil selon l'une quelconque ou plusieurs des revendications 13 à 15, caractérisé en ce que la différence entre les vitesses périphériques du cylindre pourvu de projections et du cylindre lisse peut être réglée.

17. Appareil selon l'une quelconque ou plusieurs des revendications 13 à 16, caractérisé en ce que la pression entre les deux cylindres peut être réglée.

18. Appareil selon l'une quelconque ou plusieurs des revendications 13 à 17, caractérisé en ce que le cylindre (7) pourvu de projections (P1, P2) présente une surface extérieure qui comporte des zones pourvues de projections et de zones qui sont lisses. 5
19. Appareil selon l'une quelconque ou plusieurs des revendications 13 à 17, caractérisé en ce que le cylindre (7) pourvu de projections comporte des zones (21) avec des projections plus hautes (23) et des zones (25) avec des projections plus basses (27). 10
20. Appareil selon l'une quelconque ou plusieurs des revendications 13 à 19, caractérisé en ce que le cylindre lisse (5) comporte une surface cylindrique élastique se composant d'un revêtement (5A) d'un matériau de caoutchouc ou d'une fibre textile. 15
21. Appareil selon l'une quelconque ou plusieurs des revendications 13 à 19, caractérisé en ce que la surface extérieure du cylindre lisse (5) est réalisée en métal. 20
22. Bande ou film (N) comportant une pluralité de perforations formant des trous (F) traversant ladite bande, le matériau de la bande ou du film, qui a été retiré au niveau de chacun desdits trous (F) étant partiellement détaché du matériau de base de ladite bande et formant un toron (A) s'étendant à partir d'une surface de ladite bande ou film, et 25
- le matériau dudit toron (A) étant plastiquement déformé,
 - et le matériau de base étant plus épais au niveau de la partie du périmètre du trou où ledit toron est relié audit matériau de base que dans la partie du périmètre où le toron est détaché dudit matériau de base; 30
- caractérisé en ce que 40
- le toron (A) se projette sur le trou correspondant (F). 45
23. Bande ou film selon la revendication 22, caractérisé(e) en ce qu'elle/il est formé(e) par une seule couche de film plastique. 50
24. Bande ou film selon la revendication 22, caractérisé(e) par une structure multicouches, comprenant une couche de film plastique intermédiaire et des couches extérieures composées de fibres, ou une structure monocouche de fibres tissées ou non tissées. 55
25. Matériau de bande selon l'une quelconque ou plusieurs des revendications 22 à 24, caractérisé en ce qu'il comporte des zones perforées (A1) et des zones non rompues (A2).
